

1. Color gloss differentiation of door interior components

Different colored interior parts must be differentiated. The color differences between the respective components are relatively small but there is a good difference in the gloss factor due to the different structure of the part. There is a proper differentiation possible with the color-gloss sensor **SPECTRO-3-50-FCL** as shown in the screen shots. The distance from the sensor to the object is approximately 85 mm. The pictures shows the three different black components.
